

FIG. 1. (a) Modeled  $\varepsilon_1$  and  $\varepsilon_2$  spectra for CuIn<sub>0.7</sub>Ga<sub>0.3</sub>Se<sub>2</sub> taken at 40 K (solid blue lines) and 300 K (dashed red lines). Four prominent above-bandgap CP features are indicated by arrows, which are labeled in the numeric and alphabetic order. (b) The  $\varepsilon$  spectra for CuIn<sub>0.5</sub> Ga<sub>0.5</sub>Se<sub>2</sub> calculated by the FPLAPW using the GGA + U. The major CP features corresponding to the SE results are identified.

Fig. 1(a). For both temperatures, the optical structures associated with the  $E_1$ ,  $E_6$ ,  $E_A$ , and  $E_C$  interband CPs are clearly seen in the  $\varepsilon_2$  spectra at around 3.0, 3.8, 4.8, and 5.5 eV. In the 40 K spectra, however, the CP features are better resolved and their energies increase slightly from those in the 300 K data. For example, the  $E_C$  CP feature at  $\sim$ 5.5 eV is seen only as a weak shoulder in the  $\varepsilon_2$  spectra at 300 K, but it appears as a distinct peak in the 40 K data. We note that Alonso *et al.*9 identified the electronic origins of the CP features observed in their room-temperature SE data based on the results from density functional theory calculations done by Jaffe and Zunger. The  $E_1$ ,  $E_6$ , and  $E_A$  CPs in our data may correspond to the  $E_1(A)$ ,  $E_1(B)$ , and  $E_2(A)$  CPs in Ref. 9.

The overall shape of the SE-determined  $\varepsilon$  data shows a good agreement with the averaged  $\varepsilon = [2\varepsilon_{\perp} + \varepsilon_{\parallel}]/3$  spectrum for  $\text{CuIn}_{0.5}\text{Ga}_{0.5}\text{Se}_2$  calculated by the FPLAPW method with the GGA+U potential that is presented in Fig. 1(b). The ordinary  $(\varepsilon_{\perp})$  and extraordinary  $(\varepsilon_{\parallel})$  components of the  $\varepsilon$  were calculated in our previous work. It appears that the theory slightly underestimates the CP energies below  $4\,\text{eV}$ , but overestimates those above  $4\,\text{eV}$ . Although the Ga/(Ga+In) ratio x for the experimental data (x=0.3) and calculated spectrum (x=0.5) are different, our calculations suggest that no significant difference in the optical properties is anticipated between those two close compositions, other than the shift of CP energies. This is also evidenced by the similarities in the calculated  $\varepsilon$  spectrum and the CP features between  $\text{CuIn}_{0.5}\text{Ga}_{0.5}\text{Se}_2$  and  $\text{CuInSe}_2$ .

For the analyses of the observed CP features, we numerically calculated second-energy-derivatives of the pseudodielectric function  $\langle \epsilon \rangle$  data using a Savitzky-Golay type <sup>23</sup> linear-filtering algorithm. The CP energies are obtained by assuming the standard analytic CP expressions <sup>24,25</sup> for the lineshapes and then fitting them to the data by least squares schemes. Details of the lineshape analysis procedures can be found elsewhere. <sup>13–16</sup>

The lineshape analysis for the  $40\,\mathrm{K}$  data is presented in Fig. 2. A total of twelve lineshapes were needed to analyze the data from 2.5 to 6.4 eV. The majority of the CP features are fit best with the two-dimensional lineshapes, whereas the  $E_2$ ,  $E_6$ ,  $E_B$  CPs are better represented by the excitonic lineshapes and the  $E_D$  CP is by the three-dimensional lineshape. Both real and imaginary parts are fit simultaneously. Similar fit quality was achieved for the  $300\,\mathrm{K}$  data (not shown). The

fit-determined CP energies are listed in Table I. For comparison, the CP energies for various  $\text{CuIn}_{1-x}\text{Ga}_x\text{Se}_2$  previously reported are also included. Although Alonso *et al.*9 observed the E( $\Gamma$ X) CP at  $\sim$ 2.4 eV for  $\text{CuIn}_{0.6}\text{Ga}_{0.4}\text{Se}_2$ , our data do not resolve this CP. We note, however, that we probed two additional CPs E<sub>2</sub> and E<sub>4</sub>, which have not been seen in previous room-temperature SE studies. 8–10,12

The electronic origins of each CP are examined based on the results from the FPLAPW calculations. First, we identify the different contributions to  $\varepsilon_2$  in terms of the transitions between the valence bands  $v_i$  and the conduction bands  $c_j$ . Here, the  $v_1$  and  $c_1$  denote the highest valence band and lowest conduction band, respectively. This contribution is labeled as  $v_1 \leftrightarrow c_1$  in Fig. 3. As expected, 8,9 the E<sub>0</sub> CPs in the low-energy region are associated with the transitions from  $v_1$  to  $c_1$  near the  $\Gamma$  (0, 0, 0) point of the Brillouin zone (BZ). A broad optical structure in the  $\varepsilon_2$  spectrum spanning from 5 to 7 eV is composed of several contributions from the low-lying valence bands. Therefore, unambiguous identification of the major contributions to the CP features in the high-energy region is very difficult.

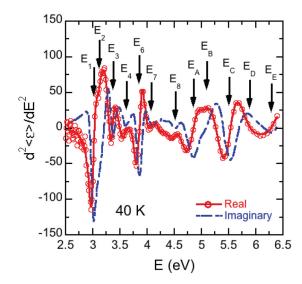

FIG. 2. (a) Solid red are standard CP lineshapes best fit to  $d^2\langle \epsilon_1 \rangle/dE^2$  (open circles) and dashed-dotted blue lines are  $d^2\langle \epsilon_2 \rangle/dE^2$ . For clarity, only half the data points are shown and the  $d^2\langle \epsilon_2 \rangle/dE^2$  are not displayed. Energies of each CP are indicated by arrows and labeled in a numeric and alphabetic order.

TABLE I. CP energies in eV for  $CuIn_{0.7}Ga_{0.3}Se_2$  at 40 and 300 K. Previously reported CP energies for various  $CuIn_{1-x}Ga_xSe_2$  are also included for comparison.

<sup>&</sup>lt;sup>a</sup>The  $E_0(A,B)$  and  $E_0(C)$  energies estimated from the modeled  $\varepsilon_2$  spectra.

Second, we analyze the k-dependence of the CPs along the main symmetry directions, which is depicted in Fig. 4. The pronounced  $E_1$  CP originates from the  $v_1 \rightarrow c_1$  transitions near the P ( $^1/_2$ ,  $^1/_2$ ) point of the BZ (in the conventional coordinates). This is consistent with the results from room-temperature SE studies by Alonso  $et\ al.$ ,  $^{8,9}$  where this CP is assigned to the  $E_1(A)$  CP. We observed a small doublet

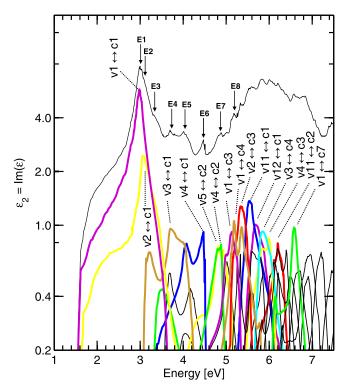

FIG. 3. Band-to-band analysis of the contribution to the total  $\varepsilon_2$  spectrum (thin black trace). The most important valence-to-conduction band transitions ( $v_i \rightarrow c_j$ ) are marked by thick colored curves. Spin-orbit interaction is included, and the band-to-band transitions involve a summation of the spin up and down contributions. Note: The vertical axis  $\varepsilon_2$  is in the log scale.

structure in the E<sub>1</sub> peak arising from the spin-orbit split. The E<sub>2</sub> and E<sub>3</sub> CPs involve transitions from the second valence band,  $v_2 \rightarrow c_1$ . This band-to-band transition generates two structures in  $\varepsilon_2$ , where the main peak is associated with transitions at the P-point as for the E<sub>1</sub> CP. In CuIn<sub>0.5</sub>Ga<sub>0.5</sub>Se<sub>2</sub>, the  $E_2$  and  $E_3$  peaks modify only slightly the main  $\varepsilon_2$  spectrum around 3.2 eV. However, the calculations for CuInSe<sub>2</sub> reveal that the E<sub>2</sub> and E<sub>3</sub> CPs occur 0.1–0.2 eV higher than the E<sub>1</sub> CP, and appear as distinct spectral features. Thus, the observation of E<sub>2</sub> and E<sub>3</sub> CPs in CuIn<sub>0.7</sub>Ga<sub>0.3</sub>Se<sub>2</sub> is anticipated. The E<sub>4</sub> CP originates from the  $v_3 \rightarrow c_1$  transitions at the M  $(1, 0, 0) = M^* (0, 0, 1)$  point. The E<sub>5</sub> CP is mainly attributed to the transition to  $v_4 \rightarrow c_1$  at the N (1/2, 0, 1/2) point, but the  $v_3 \rightarrow c_1$  transitions at the M/M\* points also contribute to this CP feature. This E<sub>5</sub> CP can be understood as the E<sub>1</sub>(B) CP in previous SE studies.<sup>8,9</sup> The E<sub>6</sub> CP feature is a result of the  $v_4 \rightarrow c_1$  transition at the N point. The E<sub>7</sub> CP corresponds to the  $v_4 \rightarrow c_2$  transitions at the  $\Gamma$  (0, 0, 0) and N point, and the  $v_5 \rightarrow c_2$  transitions at the  $\Gamma$  point. The E<sub>A</sub>, another prominent CP feature equivalent to the E<sub>2</sub>(A) CP in Refs. 8 and 9, also has multiple contributions from the various symmetric points of BZ: The  $v_1 \rightarrow c_4$  transitions at the  $X^*$  ( $\frac{1}{2}$ ,  $\frac{1}{2}$ , 0) point of the BZ, and the  $v_1 \rightarrow c_3$  transitions at the N and P points. We conjecture that the  $v_{11} \rightarrow c_1$  and  $v_{12}$  $\rightarrow c_1$  transitions near the P point of BZ are the major contributions to the E<sub>C</sub> CP. Although this CP has not been discussed in previous SE studies<sup>8,9</sup> of CuIn<sub>1-x</sub>Ga<sub>x</sub>Se<sub>2</sub> probably due their limit on the spectral range, a recent real-time SE study<sup>12</sup> of CuInSe<sub>2</sub> observed a similar structure at 5.11 eV without identification of its electronic origin.

Our calculations suggest that the energy differences in the  $E_0$  transitions are  $E_0(B)-E_0(A)=0.02\,\mathrm{eV}$  and  $E_0(C)-E_0(A)=0.20\,\mathrm{eV}$  for  $\mathrm{CuIn_{0.5}Ga_{0.5}Se_2}$ , which stem from the negative crystal field split of  $\Delta_{cf}=-0.03\,\mathrm{eV}$  and a relatively large spin-orbit split  $\Delta_{so}=0.19\,\mathrm{eV}$ . From the similarities in the valence bands dispersion in  $\mathrm{CuIn_{1-x}Ga_xSe_2}$  with

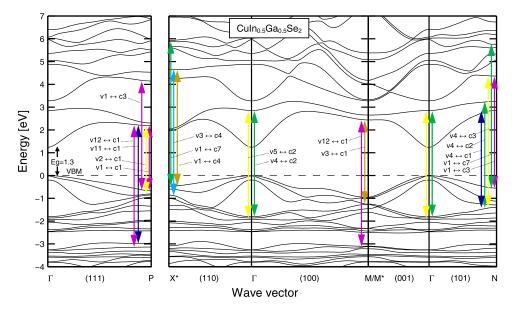

FIG. 4. The calculated electronic band structure of  $\text{CuIn}_{0.5}\text{Ga}_{0.5}\text{Se}_2$  where the CPs are identified along the main symmetry directions. Contributions of individual CPs to the  $\varepsilon_2$  are shown in Fig. 3.

different alloy compositions, <sup>26</sup> one may expect  $\Delta_{cf} \approx 0 \, \text{eV}$  and  $\Delta_{so} \approx 0.2 \, \text{eV}$  for  $\text{CuIn}_{0.7} \text{Ga}_{0.3} \text{Se}_2$ , which is consistent with our experimental observation.

In summary, the  $\varepsilon$  spectra for CuIn $_{0.7}$ Ga $_{0.3}$ Se $_2$  were determined by spectroscopic ellipsometry at 40 and 300 K. From a standard lineshape analysis of ellipsometric data, a total of twelve CP energies were obtained from 2.5 to 6.4 eV, which include two additional CPs at 3.01 and 3.48 eV. Electronic origins of the observed CP features were discussed based on the results from FPLAPW calculations of the electronic band structure for CuIn $_{0.5}$ Ga $_{0.5}$ Se $_2$ . The pairs of valence and conduction bands along the main symmetry directions of Brillouin zone were suggested for the major CP features observed in the  $\varepsilon_2$  spectra.
